Subdural Hematoma Resolution After MMA Embolization

Time course of hematoma resolution following middle meningeal artery embolization

Generated from the neurosurgery textbook corpus · decision-support only · 2026-06-14

Based on the provided sources:

A specific time course for the resolution of subdural hematomas (SDH) following middle meningeal artery (MMA) embolization is not detailed. However, the sources do provide some information on outcomes at follow-up.

- A multicenter study of 154 embolizations showed that on follow-up imaging, 70% of patients had a greater than 50% reduction in hematoma size [3, 4]. In this same study, 6.5% of patients experienced further expansion of the hemorrhage that required drainage [3]. The exact timing of this follow-up is not specified [3].
- One case example shows resolution of a right-sided chronic SDH on a subsequent CT scan after embolization of the right MMA was performed [1]. Figure 3.9 from this source shows an axial FLAIR image (A) with bilateral complex subdural hematomas, a sagittal CT MIP reformat (B) with evidence of embolic material in the right MMA, and a subsequent axial CT (C) demonstrating resolution of the right-sided hematoma [1]. The time interval between the procedure and the follow-up scan is not stated [1].
